Longshore velocity component

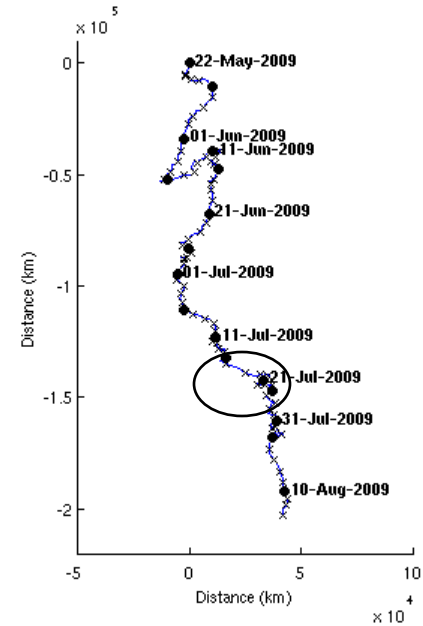

Wind progressive vector diagram

# Simulations

- Mars3D model
- Grid size : 2km, 50 sigma levels
- 2 domains. Continental shelf slopes : 0.44% (spanish coast), 0.22% (french coast)
- Density field : 22°C from surface to 30m, Thermocline of 10m, 12°C below 40m
- Forcing : 3 days of 10m/s westerlies

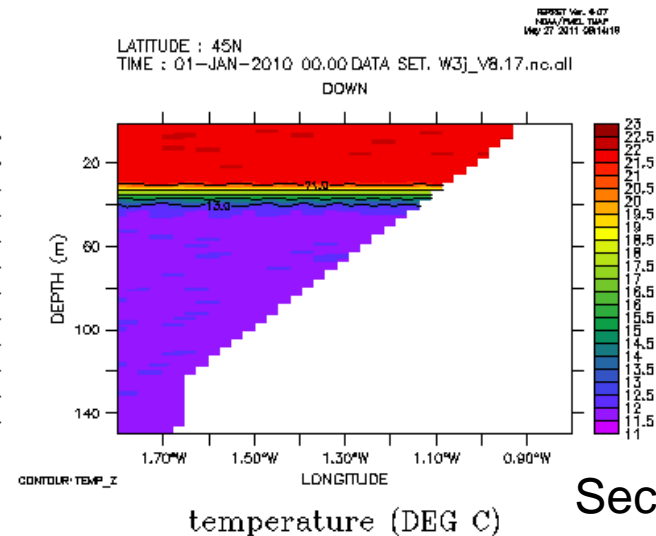

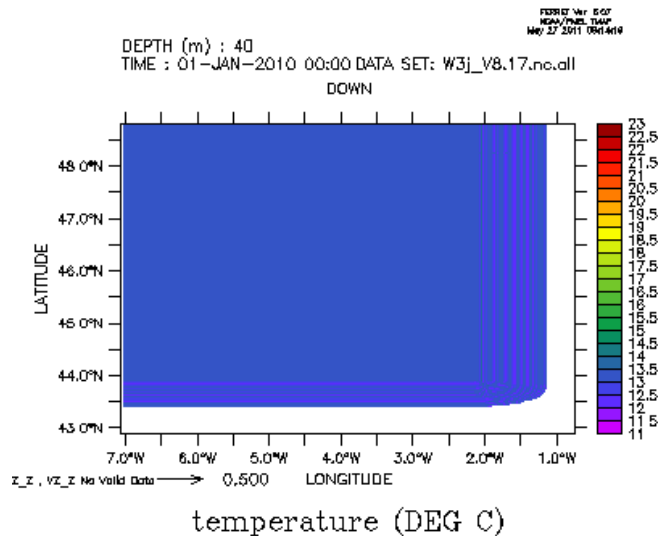

# Base case

Surface

Spanish section(2°W)

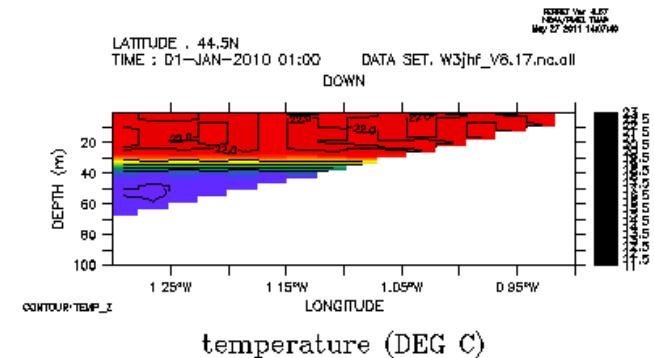

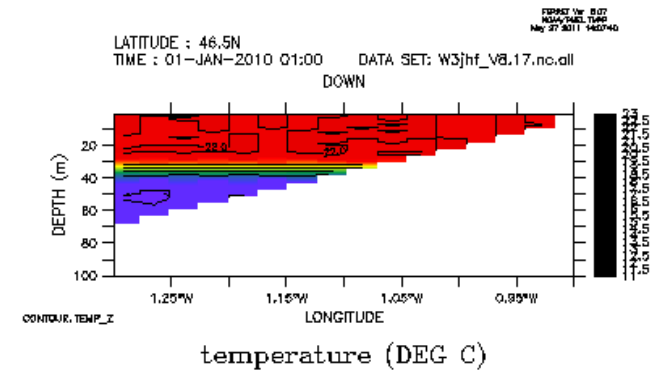

40m

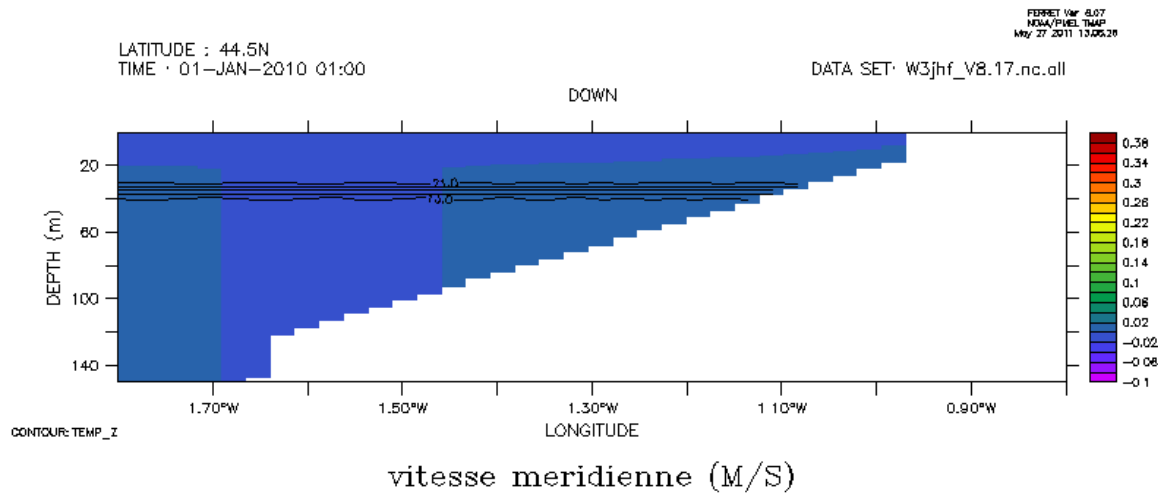

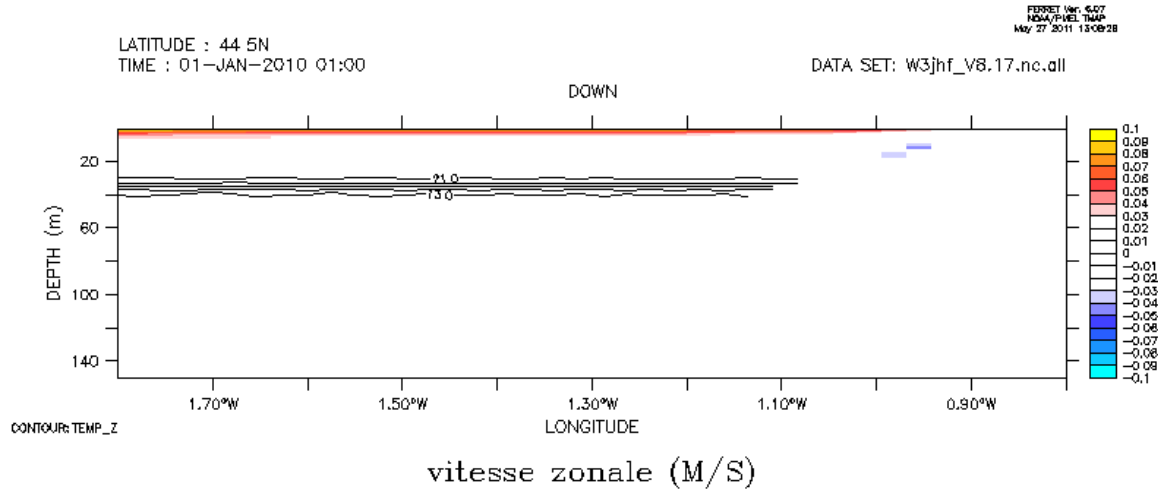

Section at 44.5°N

# Along the french coast

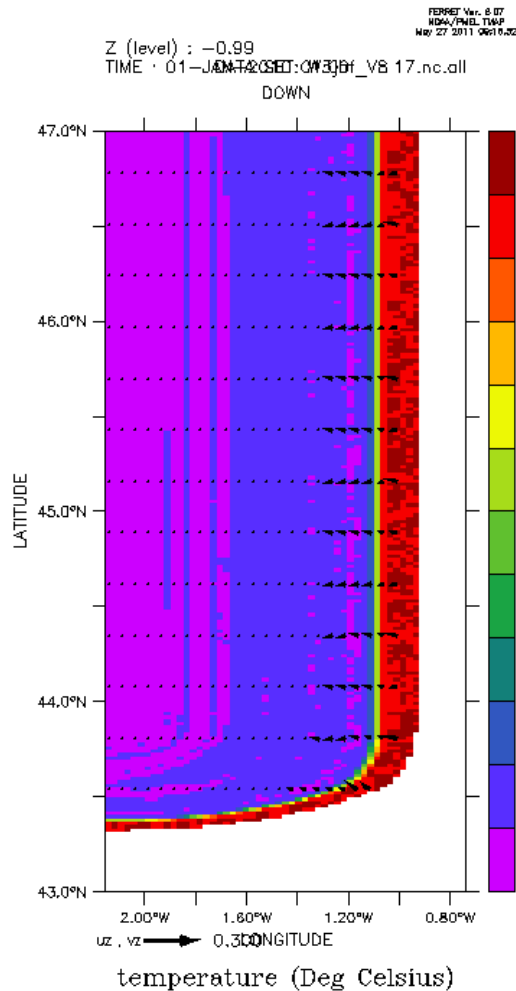

- Downwelling circulation
- The bottom front moves downslope
- Strong poleward circulation over the bottom front

# Transect at 44.5°N

# Zoom on the Landes coast

Bottom  
temperature  
and currents

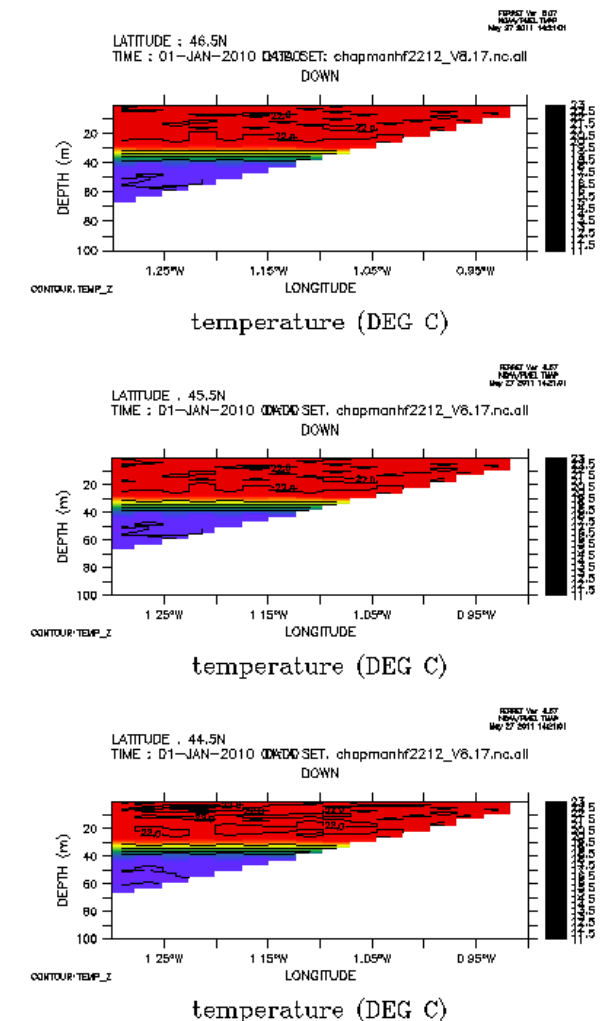

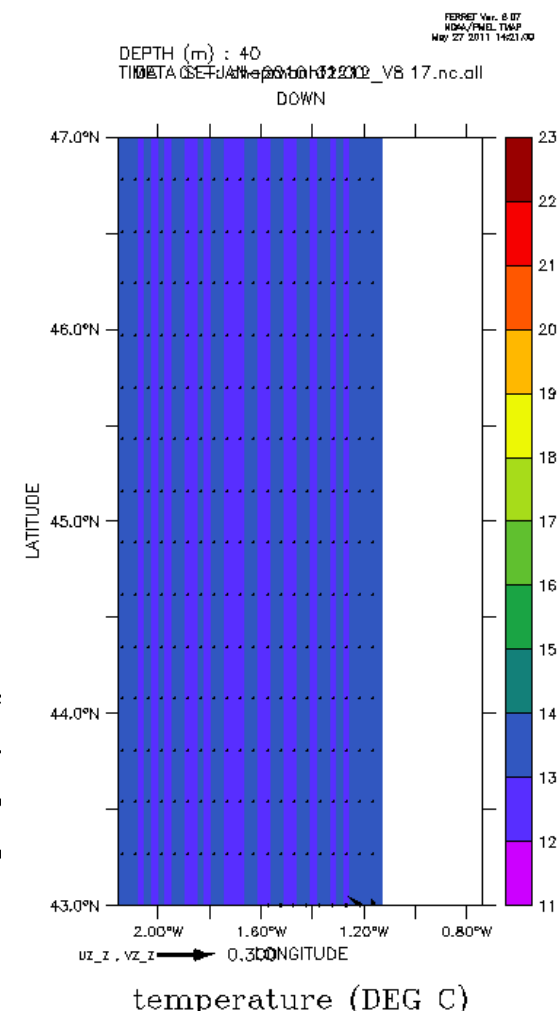

Sea  
Surface  
Height

# Straight coastline Simulation

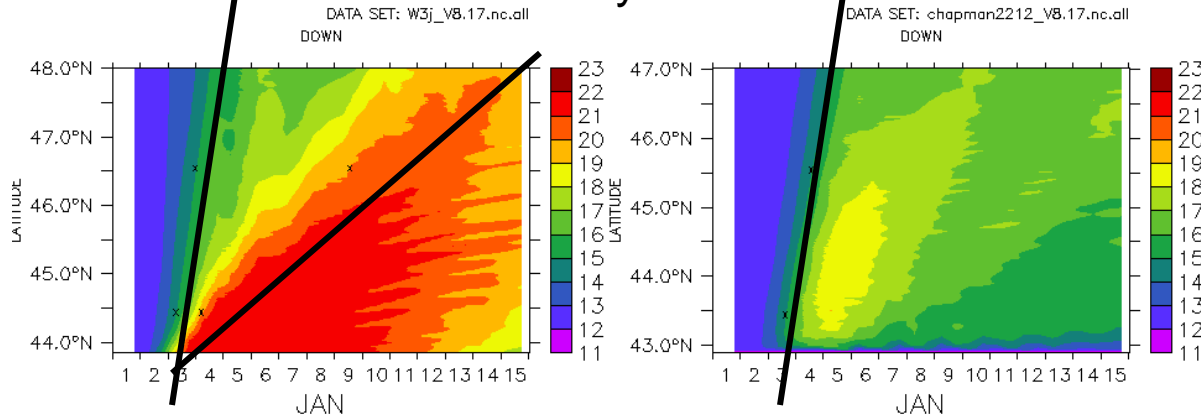

## Boundary conditions :

- No wind
- Southern boundary : rise of SSH to 12cm in 3 days and back to 0 cm

# Time evolution of bottom temperature along transects

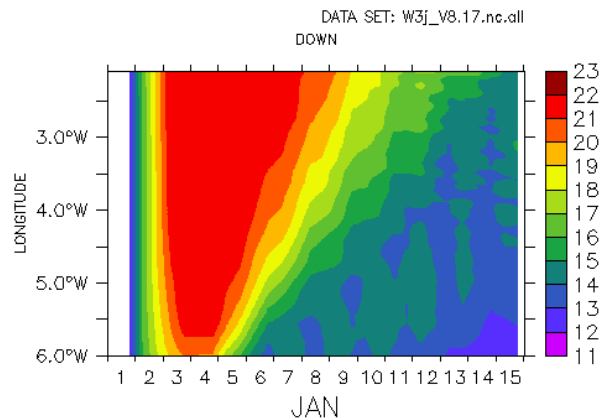

200km/day $\approx$ 2m/s    33km/day $\approx$ 30cm/s

(b)

(c)

- Diagram of bottom temperature at depth of 50m:

(a)

- a: Base case :along Spanish coast
- b : Base case : along Landes coast
- c : Straight coastline

# Conclusions

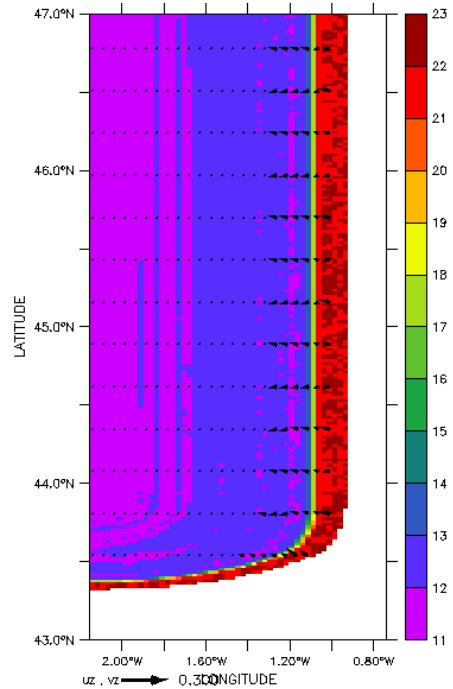

- Few days of westerlies => Downwelling circulation along the spanish coast
- Rise of SSH, maximum of 15cm in the SE corner
- Downwelling like circulation along the coast of Landes => offshore displacement of bottom front and rise of bottom temperature
- Advection of warm water from South
- Sensitivity analysis ( wind duration and direction, stratification,...)

# Next step : Assessment of the advection of warm bottom water

# Next step : Assessment of the advection of warm bottom water

Evolution of bottom temperature at 44.5°N, 46°N and 47°N

- Need to be assessed :
  - Role of the frictional effects of tides
  - Widening of the shelf
- Realistic simulations of Aspex observed episodes
